

NEW ABSTRACT

Print service receiving server or servers are connected to a network. A user, in case of requesting print of digital image data recorded on a recording medium, mounts the recording medium onto a terminal. On the recording medium, connection address data to the specified server and data indicating a specified service shop are recorded. When the recording medium is mounted, the terminal connects through the network to the server and transmits print request data (service shop data, requester, the requested number of prints and the like) together with the digital image data to be printed, and the server sends other data than the service shop data to a service shop.
